

AI Agents vs Agentic AI

Exploring key concepts

AI Agents in Action

What Are AI Agents?

A system that:

1. **Perceives** its environment (through input like text, images, audio, etc.),
2. **Thinks or reasons** (uses AI models or logic to understand),
3. **Acts** to achieve goals (responding, performing actions, generating results)

E.g. While an LLM can generate code, we can equip it with a **code interpreter tool**. This allows it to not only write code but also **run it and respond with the computed result (reduces hallucination)**.

So, if we ask, “*Find the 345th Fibonacci number,*” the agent:

- Writes the code.
- Executes it using the interpreter,
- And returns the computed answer accurately.

Key Features of AI agents

- Reactive, responding to predefined triggers or user requests.
- Limited autonomy and learning
- Often powered by Large Language Models (LLMs as brain) with tools (custom functions) or evolving toward Specialized Language Models (SLMs) for specific tasks.

What is Agentic AI?

Agentic AI represents recent advanced form of artificial intelligence that operates autonomously. It can make decisions, set its own goals, and adapt to new situations with minimal or sometimes without human guidance.

Key Features of Agentic AI

- High autonomy, with the ability to make decisions and set goals independently.
- Proactive, identifying needs or opportunities without too much explicit prompts.
- Capable of coordinating multiple systems or agents for complex tasks.

Characteristics Comparison

Parameters	AI Agents	Agentic AI
Autonomy	Operate within strict boundaries defined by their programming.	Exhibits significant autonomy, capable of making decisions and taking actions without human explicit prompts.
Task Complexity	Designed for specific, often repetitive tasks with predictable outcomes.	Handles complex, multi-step processes that require reasoning across domains.
Learning and Adaptation	Have limited learning capabilities, typically improving through developer updates/prompts or learning within a narrow domain.	Learns from a wide range of interactions and experiences, adapting to new situations and even setting new goals.
Proactiveness	Reactive by nature, they act only when triggered by user inputs or predefined conditions.	Proactive, capable of identifying opportunities or issues.
Integration and Scale	Often standalone tools or components within a larger system, focused on specific functions.	Acts as an umbrella technology, integrating multiple AI Agents or tools to achieve broader objectives.
